# Context: costly shape optimization I

This study is presented with details in [Gaudrie et al., 2020].

Minimize the drag of an airfoil by changing its shape

$\min_{\phi \in \mathcal{S}} f(\phi)$  ,  $\mathcal{S}$  “infinite” dimensional space of shapes

NACA 23012

NACA 63<sub>1</sub>-412

NACA 66<sub>1</sub>-212

from <https://history.nasa.gov/SP-468/ch5-2.htm>

# Context: costly shape optimization II

## Computational practice

**design:** decide shape parameters  $x \in \mathbb{R}^d$

**CAD:** translate them into a shape  $\phi(x) \in \mathbb{R}^D$ ,  $D \gg d$

not costly

**simulate:** calculate  $f(\phi(x))$ , e.g., by Navier-Stokes resolution

costly

# Context: costly shape optimization III

A straightforward resolution of  $\min_{x \in \mathcal{S} \subset \mathbb{R}^d} f(\phi(x))$  is difficult: the problem dimension  $d$  (10-100) is too large considering the computing time of  $f$  (minutes to hours).

In this work, tackle this problem through,

- A) dimension reduction from  $\phi(x)$  by eigenshape decomposition
- B) metamodeling with Gaussian process (GP) including supervised dimension reduction (from  $f$ ),
- C) optimization in the reduced-dimension space of A) and B).

# Intrinsic dimension reduction by eigendecomposition

Creating shapes without evaluating their performance is fast  $\Rightarrow$  calculate a hierarchical basis of eigenvectors in shape space by PCA (a.k.a. POD)

- sample CAD parameters  $x^i \sim \mathcal{U}(\mathcal{S})$ ,  $i = 1, \dots, N$ ,  $N \gg d$
- calculate the shapes  $\phi(x^i)$ ,  $i = 1, \dots, N$  and create  $\Phi = [\phi(x^1) \dots \phi(x^N)]$
- PCA:  $(\lambda_i, V^i)$  (eigenvalues, eigenvectors) of  $\frac{1}{N} \Phi \Phi^T$  with  $\lambda_1 \geq \dots \geq \lambda_D \geq 0$
- Keep dimensions  $(V^1, \dots, V^\delta)$  where  $\delta$  smallest integer such that  $\frac{\sum_{i=1}^{\delta} \lambda_i}{\sum_{i=1}^N \lambda_i} > 0.99$

$V^i$ :  $D \times 1$  “eigenshape” (but it may not be a feasible shape)

# Airfoils eigenshapes

From a database of possible airfoils  $[\phi(x^1), \dots, \phi(x^{5000})]$ ,

...

extract  $\delta = 20$  eigenshapes  
 $\{V^1, \dots, V^\delta\}$

# Working with the eigencomponents $\alpha$

Shapes are now described with their eigencomponents  $\alpha$ 's:

$$\phi \approx \bar{\phi} + \sum_{i=1}^{\delta} \alpha_i V^i \quad \text{and} \quad \alpha_i = (\phi - \bar{\phi})^\top V^i$$

$(\alpha_1, \dots, \alpha_\delta)$  make a specific manifold

Cf. also [Raghavan et al., 2013, Li et al., 2018, Cinquegrana and Iuliano, 2018]

# $\delta$ and the intrinsic dimension

[Gaudrie et al., 2020]: with  $\phi(x)$  a vector of discretized contour points (as opposed to characteristic functions and signed distances),

$\delta =$  dimension of the  $\alpha$  manifold  $\approx$  empirical intrinsic dimension of the shapes

$\alpha$ 's

- A) dimension reduction from  $\phi(x)$  by eigenshape decomposition
- B) **metamodeling with Gaussian process including supervised dimension reduction (from  $f$ )**
- C) optimization in the reduced-dimension space of A) and B)

# GP approximation with dimension reduction I

Approximate  $f(\phi)$  (the drag) with a GP  $Y(\alpha)$  where  $\alpha = V^T(\phi - \bar{\phi})$

$Y(\alpha)$  learns the database  $\underbrace{[\alpha^i = V^T(\phi(x^i) - \bar{\phi}), f(\phi(x^i))]}_{[\alpha, \mathbb{F}]}, i = 1, N$

# GP approximation with dimension reduction II

- The GP is mainly controlled through its kernel,  $k(\alpha, \alpha') = \text{Cov}(Y(\alpha), Y(\alpha'))$
- Kernels are parameterized by  $\theta$ 's and  $\sigma^2$
- **Anisotropic** kernels have 1  $\theta_i$  per dimension  
Expl:  $k_{\text{ani}}(\alpha, \alpha') = \sigma^2 \exp\left(-\sum_{i=1}^{\delta} \frac{(\alpha_i - \alpha'_i)^2}{\theta_i^2}\right)$
- **isotropic** kernels have 1  $\theta$  for all dimensions  
Expl:  $k_{\text{iso}}(\alpha, \alpha') = \sigma^2 \exp\left(-\frac{(\alpha - \alpha')^2}{\theta^2}\right)$
- Kernel parameters are learned by maximizing the likelihood of  $[\alpha, \mathbb{F}]$

# GP approximation with dimension reduction III

- A likelihood that favors sparsity [Yi et al., 2011]:

$$\theta^* = \arg \max_{\theta} \text{Log-Likelihood}(\theta; \alpha, \mathbb{F}) - \lambda \|\theta^{-1}\|_1$$

⇒ active and non-active dimensions,  $\alpha_a$  and  $\alpha_{\bar{a}}$ .

$$a = \{i \in [1, \dots, \delta] \mid \theta_i^* < M \gg 1\}$$

$$\bar{a} = \{1, \dots, \delta\} \setminus a$$

# GP approximation with dimension reduction IV

- GP as the sum of an anisotropic and isotropic GPs [Allard et al., 2016], accurate on the active dimensions, plain but sparse otherwise:

$$k(\alpha, \alpha') = k_{\text{ani}}(\alpha_a, \alpha'_a) + k_{\text{iso}}(\alpha_{\bar{a}}, \alpha'_{\bar{a}})$$

Expl NACA22 :

$$\alpha_a = \{\alpha_1, \alpha_2, \alpha_3\}, \quad \delta_a = 3, \quad \delta = 20 \\ \Rightarrow 20 \text{ to } 6 \text{ kernel parameters}$$

20:  $\theta_1$  to  $\theta_{\delta=20}$ ,  $\sigma^2$  by likelihood concentration formula.

6: 3  $\theta_a$ 's, 1  $\theta_{\bar{a}}$ ,  $\sigma_{\text{iso}}^2$ ,  $\sigma_{\text{ani}}^2$

- A) dimension reduction from  $\phi(x)$  by eigenshape decomposition
- B) metamodeling with Gaussian process including supervised dimension reduction (from  $f$ )
- C) optimization in the reduced-dimension space of A) and B)

# Optimizing with GPs

Measure of progress: the improvement,

$$I(x) = \max[0, \min(\mathbb{F}) - Y(\alpha)]$$

Optimization scheme : maximize the expectation of the improvement at each iteration and update the GP

$\mathbb{E}I = 0$  at data points,  
pushes the search away  
from them

# Reduced dimension search

Search the full active space and search along a 1D random linear embedding in the inactive space

$$\alpha^{(t+1)*} = \arg \max_{[\alpha_a, \bar{\alpha}]} \mathbb{E} /$$

$\bar{\alpha}$  coordinate along a random line in non-active space,  
 $\delta_a + 1$  dimensions.

## GP update: pre-image problem

To calculate the new objective function,  $\alpha^{(t+1)*}$  needs to be transformed into a CADable shape = pre-image problem = projection of  $V\alpha^{(t+1)*} + \bar{\phi}$  onto the closest CAD shape

$$x^{(t+1)} = \arg \min_{x \in \mathcal{S}} \|V\alpha^{(t+1)*} + \bar{\phi} - \phi(x)\|^2$$

and evaluate  $f(\phi(x^{(t+1)}))$

The next feasible eigencomponents are

$$\alpha^{(t+1)} = V^T (\phi(x^{(t+1)}) - \bar{\phi})$$

# GP update: replication

Incentive for the optimization to search into the  $\alpha$ -manifold: put the datapoint outside the manifold as  $\mathbb{E}f$  will be null there afterwards

## Replication

Update the GP with both  $\alpha^{(t+1)*}$  and  $\alpha^{(t+1)}$ :

$$[\alpha, \mathbb{F}] \leftarrow [\alpha, \mathbb{F}] \cup [\alpha^{(t+1)}, f(\phi(x^{(t+1)}))] \cup [\alpha^{(t+1)*}, f(\phi(x^{(t+1)}))]$$

# Example: NACA 22 airfoil drag minimization

NACA22: Drag optimization in reduced eigenshape basis

NACA22: Drag optimization in CAD parameters space

NACA22: Best observation

- Faster decrease of the objective function in the reduced eigenshape basis (left) compared with the standard approach (right, CAD parameter space).
- Smoother airfoils are obtained because a shape basis is considered instead of a combination of local parameters.

## Summary

- We have mixed two dimension-reduction techniques: PCA and subsequent searching into an  $\alpha$ -manifold (replication); the identification of an inactive subspace where sparse learning and searching is done (additive kernel and linear embedding).

## Perspectives

- Why is the PCA dimension reduction working so well in our cases of CAD-like shape parameters?
  - The approach is not specific to shapes and would apply any objective function composed as  $f(\phi(x))$
- ⇒ try other cases, e.g. functional inputs.
- Investigate the 2 ideas (PCA . . . , inactive space identification . . . ) separately.
